Abstract

The spin-web compound Cu₃TeO₆, belongs to an intriguing group of materials where magnetism is governed by 3d⁹ copper Cu²⁺ ions. This compound has been sparsely experimentally studied and we here present the first investigation of its local magnetic properties using muon-spin relaxation/rotation (μ⁺SR). Our results show a clear long-range 3D magnetic order below T_N as indicated by clear zero-field (ZF) muon-precessions. At T_N = 61.7 K a very sharp transition is observed in the weak transverse-field (wTF) as well as ZF data. Contrary to suggestions by susceptibility measurements and inelastic neutron scattering, we find no evidence for either static or dynamic (on the time-scale of μ⁺SR) spin-correlations above T_N.

Keywords: Muon-spin relaxation/rotation (μ⁺SR), spin-web compounds, short-range magnetic order

1. Introduction

Although magnetism is a quantum phenomenon, properties of most of the magnetic insulators can be understood using a semi-classical approach, i.e. the linear spin-wave theory. Especially in three-dimensional (3D) systems quantum effects are expected to be small and it may be asked whether they are at all relevant. The insulating tricopper-tellurate Cu₃TeO₆ belongs to an intriguing group of compounds where the magnetism is governed by 3d⁹ copper Cu²⁺ ions [1]. This compound can be indexed by the cubic space group Ia₃ [a = 9.537(1) Å] [2,3]. As shown in Fig. 1, the unit cell consists of 8 regular TeO₆ octahedra and 24 copper ions [3]. Each copper ion is surrounded by six oxygen ions forming a very irregular octahedron. There have been very few experimental studies of Cu₃TeO₆ and in fact only one published investigation is to be found regarding its magnetic properties [4]. The susceptibility-vs.-T [χ(T)] curve [inset of Fig. 2(b)] displays a kink at T ≈ 60 K indicating long-range magnetic ordering. From a wider temperature range, a good fit of χ⁻¹ to a Curie-Weiss law (CWL) for T = 180 - 330 K gives Θ_CW = -134 K [Fig. 2(b)]. This shows that the Cu²⁺ spins are in fact strongly antiferromagnetically (AF) coupled. It is further evident that χ(T) also starts to deviate from CWL below approximately 180 K, possibly indicating the onset of a short-range spin order. To

display a deviation from CWL as high as $3T_N$ is rather unusual for a 3D system and is only expected to be observed in low-dimensional and frustrated spin systems. The explanation is found in the magnetic structure that consists of a 3D “spin-web” lattice of $S = 1/2$ Cu$^{2+}$ ions characterized by low connectivity. Here each spin has only 4 nearest neighbors and 4 next-nearest neighbors, which is comparable to the two-dimensional square lattice antiferromagnet (2DSL-AF). Further, the magnetization vs. magnetic field ($H$) curve displays anomalous behavior that cannot be explained by a simple spin-flip or spin-flop transition, but rather by field induced rotation of magnetic domains. Such situation is also supported by torque measurements [4]. Neutron powder diffraction show clear magnetic peaks below $T_N$ [4] and the magnetic structure is found to be a collinear (possibly canted) Néel order on a bipartite lattice with a wave vector $\mathbf{k} = (0, 0, 0)$. The ordered moment determined by neutron diffraction is predominantly directed along the ($\pm 1$, $\pm 1$, $\pm 1$) space diagonals and is found to be only 0.64 $\mu_B$/ion, i.e. strongly reduced from the classical 1 $\mu_B$/ion, again similar to the $S = 1/2$ 2DSL-AF. Further, a recent inelastic neutron scattering (INS) study of the magnon dispersion in Cu$_3$TeO$_6$ show a large amount of diffuse scattering for $T > T_N$ [5]. In similarity to the deviation from CWL this could possibly indicate the presence of short-range spin correlations above the bulk magnetic transition. Muon-spin relaxation/rotation ($\mu^+\text{SR}$) is an optimal technique to study such microscopic magnetic properties and we here present, to the best of our knowledge, the first $\mu^+\text{SR}$ investigation of the Cu$_3$TeO$_6$ compound.

2. Experimental Details

Single crystals of Cu$_3$TeO$_6$ can be obtained by a HBr chemical transport method resulting in prisms of approximately 2x2 mm, or even bigger. For this $\mu^+\text{SR}$ experiment, a single piece of single crystal (4x4x2 mm$^3$) was attached to a low-background (fork-type) sample holder [see Fig. 2(a)] using very thin Al-coated Mylar tape. In order to make certain that the muon stopped primarily inside the sample, we ensured that the side facing the muon beamline was only
covered by a single layer of mylar tape. Subsequently, \(\mu^+\)SR data was acquired as a function of temperature. In Fig. 4(a) and from the temperature dependencies of \(f_i\) [Fig. 4(c)], as \(T\) increases the oscillation frequencies are gradually slowing down and finally disappears around \(T_N\). The magnetic order parameter [Fig. 4(c)] was found to be well fitted to the commonly used phenomenological formula:

\[
f_i(T) = f_{T \to 0 K} \left[ 1 - \left( \frac{T}{T_N} \right)^\alpha \right]^{\beta},
\]

where \(\beta\) is a parameter describing the dimensionality of the magnetic order [7]. In these fits \(T_N\) was fixed to 61.7 K as obtained from the wTF measurements and the values of \(\beta\) was shown to range from 0.4-0.5. Contrary to the proposed 2DSL-AF nature, on the length-scale of \(\mu^+\)SR, such \(\beta\)-values indicate a fully 3D (possibly Heisenberg) type magnetic order [7]. Further, that all \(f_i\)’s show the same temperature evolution (i.e. similar \(\beta\) and transition temperature) suggests that the multiple frequencies are not caused by the coexistence of different magnetic phases but rather a result of several inequivalent interatomic muon stopping sites within the crystallographic lattice. Noteworthy is also that the initial phases \(\phi_i\) in Eq. (1)] of the precession frequencies show (if not fixed) strong deviations from zero and in addition complex \(T\)–dependencies. Such non-zero phases along with a rather asymmetric field distribution

[see e.g. the FFT spectrum in Fig. 3(c)] could be an indication for incommensurate magnetic order in this compound. However, it is more likely that such phase-delays are caused by a wide field distribution due to the large amount of inequivalent muon sites, as we have previously reported for the LiCrO$_2$ compound [8]. This is clearly also in line with the neutron diffraction data that indeed show a clear commensurate order [4].

Finally, the ZF data obtained just above $T_N$ [$T = 70$ K in Fig. 4(a-b)] show no indication of short-range magnetic order. Instead it is well fitted by a simple static Gaussian Kubo-Toyabe (KT) function [$G^{KT}(\Delta_{KT}, t)$] multiplied by an exponential relaxation:

$$A_0 P_{ZF}(t) = A_{KT} G^{KT}(\Delta_{KT}, t) \cdot e^{-\lambda_{elec} t},$$

Here $G^{KT}(\Delta_{KT}, t)$ originates from the presence of randomized (nuclear) magnetic moments. From such fit we obtain $\Delta_{KT} = 0.095$ MHz along with $\lambda_{elec} = 0.009$ MHz for $T = 70$ K. The negligible value of $\lambda_{elec}$ indicates the absence of any strong fluctuations in the electronic moments (spins).

4. Summary

We here present the first study of local magnetic properties of the spin-web compound Cu$_3$TeO$_6$. On the length-scale of $\mu$SR, both wTF and ZF measurements show a clear long-range 3D magnetic order below $T_N = 61.7$ K. Contrary to suggestions by susceptibility measurements and inelastic neutron scattering, we further find no clear evidence for either static or dynamic (on the time-scale of $\mu$SR) spin-correlations above $T_N$.

Acknowledgments.

This work was performed using the GPS muon spectrometer at the Swiss Muon Source (S$\mu$S) of the Paul Scherrer Institut (PSI), Villigen, Switzerland and we are thankful to the instrument staff for their support. All the $\mu$SR data was fitted using musrfit [9] and the images involving crystal structure were made using the DIAMOND software. This research was financially supported by the Swiss National Science Foundation (through Project 6, NCCR MaNEP) and Toyota Central Research & Development Labs. Inc. DA acknowledges financial support from the Romanian CNCSIS-UEFISCU Project PNIIDEI 2597/2009 (Contract No. 444).
